#3: Generalizing Logic I [Matrices & Monads]

Welcome back!

We've been thinking about relations.

A relation is a **matrix** of truth values.

$$A \xrightarrow{R} B \xrightarrow{S} C$$

$$B = \{0, 1\}, \wedge, \vee$$

$$\begin{pmatrix} R & b_1 & b_2 & b_3 \\ a_1 & 1 & 1 & 0 \\ a_2 & 0 & 0 & 0 \\ a_3 & 0 & 0 & 1 \end{pmatrix} \begin{pmatrix} S & c_1 \\ b_1 & 1 \\ b_2 & 0 \\ b_3 & 0 \end{pmatrix} \begin{pmatrix} c_2 \\ 0 \\ 1 \end{pmatrix} = \begin{pmatrix} a_1 & 1 \\ a_2 & 0 \\ a_3 & 0 \end{pmatrix}$$

Composition is matrix multiplication

$$\sum_b R_{ab} \cdot S_{bc} := \exists b. aRb \wedge bSc$$

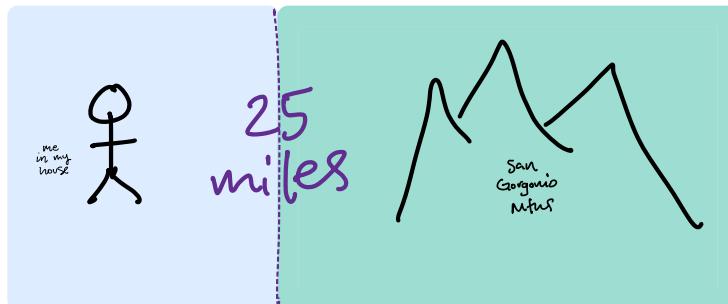

& identity is the identity matrix.

* Yet there are **many** kinds of data which can **connect** objects. *

This is the key to generalize logic.

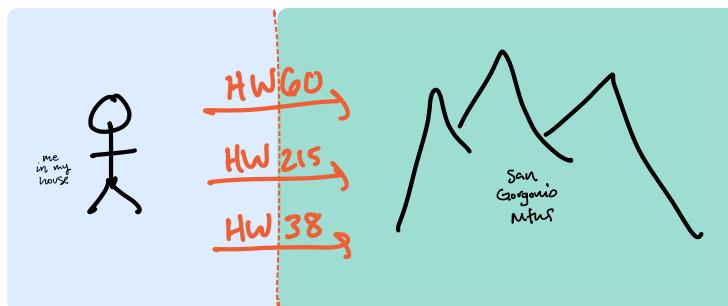

A judgement can contain rich data,
beyond just 0s + 1s:

it could be a **distance**

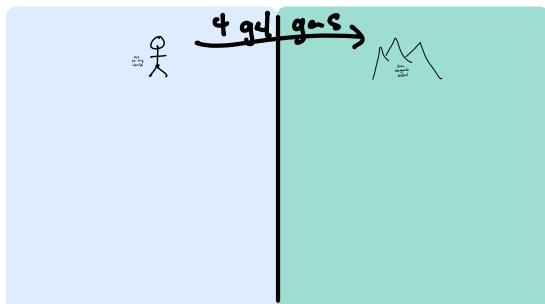

or a **set** of connections,

& much more.

What kinds of judgements can we make?

total gcs (resources, time, work)

modes of transportation

byproducts (waste, emissions)

Type Theory began with realizing
"whoa, judgements can be more than propositions."

Same here, but we just call it Logic.

The only condition is that the data compose:
as long as we have "matrix multiplication"

$$a \text{ R}^\circledast S c = \sum_{b \in B} a R b \cdot b S c \quad *$$

Set: $R^\circledast S(a, c) = \sum_{b \in B} R(a, b) \times S(b, c)$

R: $\min_{b \in B} d_R(a, b) + d_S(b, c)$

then the "kind of judgement" (which we'll call \mathbb{V})

likely forms its own kind of " \mathbb{V} -logic"!

→ just one thing: What is the "kind of inference";
what kind of structure is \mathbb{V} ?

Well, for "a notion of judgement & inference"

\mathbb{V} can be a double category
with just one type & one term.

This is a monoidal category.
multiplication

$$\begin{array}{c} x \downarrow + \downarrow y \\ \boxed{\mathbb{V}} \\ a \downarrow + \downarrow b \end{array}$$

What do we need for matrix multiplication?

"category version
of a rig"

(Set-indexed) sums, which get along with composition.

$$A \cdot \begin{array}{c} a \\ \boxed{} \end{array} \sim \left\{ \begin{array}{c} a \\ \boxed{} \end{array} \right\}_{a \in A} \quad \text{coproducts} \quad \text{distributes over sum} \quad + \quad \begin{array}{c} \circ B \cdot \begin{array}{c} b \\ \boxed{} \end{array} \end{array} = B \cdot \begin{array}{c} \circ \begin{array}{c} b \\ \boxed{} \end{array} \end{array}$$

Let's call this condition being tensored.

def Let \mathbb{V} be a tensored monoidal category.

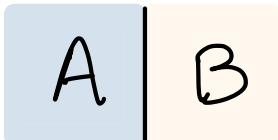

Then $\text{Mat}^{\mathbb{V}}$ is a double category:

type

A

set

judgement

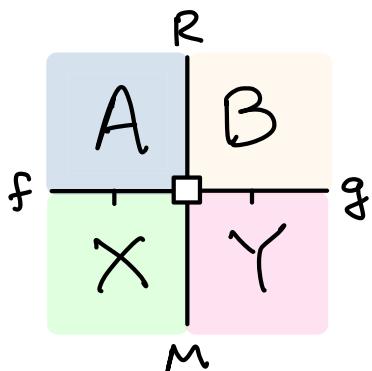

matrix
 $R: A \times B \rightarrow \mathbb{V}$

R	b	b'	...
a	•	•	
a'	•	•	
:			

↳ composition $a R S c = \sum_{b \in B} a R b \circ b S c$

↳ identity $a I a' = \begin{cases} 1 & a = a' \\ 0 & a \neq a' \end{cases}$ (1: unique type, 0: empty sum)

inference

(R	b	b'	...
a	•	•	•	
a'	•	•	•	
:				

M	y	y'	...
x	•	•	
x'	•	•	
:			

)

g(b) g(b') ...

f(a)

f(a')

$\prod_{a \in A, b \in B} R(a, b) \rightarrow M(a, b)$

↳ sequence & parallel composition. \square

$\text{Mat}^{\mathbb{V}}$ is the ground for " \mathbb{V} -valued logic."

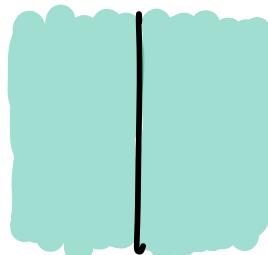

what is it like for $\mathbb{V} = (\text{Set}, \times, 1)$? $(\mathbb{R}, \leq, +, 0)$? \star

The world of Mat \mathbb{V} is nice,
but it's missing essential aspects of logic. (*) $P(X)$

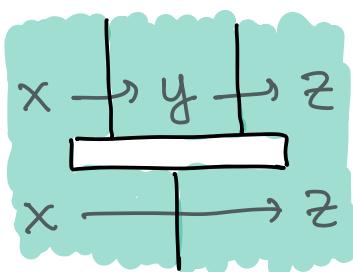

The problem is that the data of judgements
is not yet "in" the types — so far just sets. (ex)

This is an issue even for relations:
plain old sets don't "know about" implication.
* What kind of structures do?

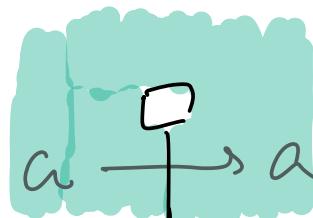

Let R be a relation
on a set A .

$$A : x \xrightarrow{R} y : A$$

composition

identity

A preorder is a set A & relation $A \xrightarrow{R} A$
with implications comp: $R \circ R \Rightarrow R$
& id: $1_A \Rightarrow R$.

This is a "monad" in Rel.

def Let \mathbb{C} be a double category.

A **monad** in \mathbb{C} is a judgement

$$A \xrightarrow{\quad} A$$

with inferences

$$\begin{array}{c} A \\ \downarrow \\ \square \end{array}$$

unit

$$aRb \cdot bRc \rightarrow aRc$$

$$\begin{array}{c} R \quad R \\ \downarrow \\ \square \end{array}$$

join

so that

$$(a \cdot b) \cdot c$$

$$\begin{array}{c} \square \\ \downarrow \\ \square \\ \downarrow \\ \square \end{array}$$

= ASSOC

$$a \cdot (b \cdot c)$$

$$\begin{array}{c} \square \\ \downarrow \\ \square \\ \downarrow \\ \square \end{array}$$

and

$$\begin{array}{c} \square \\ \downarrow \\ \square \end{array}$$

unit runit

$$\begin{array}{c} \square \\ \downarrow \\ \square \end{array}$$

□

So a monad is

"a judgement (string)
with composition & identity"

* What's a monad in $\text{Mat}(\text{Set})$? Span

$$\begin{array}{c} A \rightarrow A \\ \downarrow \\ a \not\rightarrow b \end{array}$$

$$\begin{array}{c} a \not\rightarrow b \not\rightarrow c \\ \downarrow \\ a \not\rightarrow c \end{array}$$

$$\begin{array}{c} a = a \\ \downarrow \\ a \xrightarrow{\text{id}_a} a \end{array}$$

* What's a monad in $\text{Mat}(R)$?

(lower)   
metric space!

a category!

For a double category \mathbb{C}
there's a double category of

"monads & modules" in \mathbb{C} ,

denoted $\text{Mod}(\mathbb{C})$.

For \mathbb{V} -logic, we'll explore $\widehat{\mathbb{V}} := \text{Mod}(\text{Mat}(\mathbb{V}))$.

This is a very rich world for generalized logic.

What can we learn & do in this world?

Questions / Thoughts ?

Thanks!
